5.1.2 Plots

5.1.2.1 Small batch – [5 points]

5.1.2.2 Large batch – [5 points]

5.1.3 Analysis

5.1.3.1 Value estimator – [5 points]

Q5.1.3.1

Obviously reward-to-go because of causality and smaller variance.

5.1.3.2 Advantage standardization – [5 points]

Q5.1.3.2

Yes, it does help. It helps to stabilize the learning process by reducing the variance of the advantage estimates.

One thing I don't understand is why changing the bias has no significant impact on training, since standardization changes the mean. Each reward is a function of both state and action, so moving the mean shouldn't be just like adding a state-dependent bias, e.g., V(s), right?

I guess it's because this process only "slightly" biases the advantage estimates, pretty much like the effect of not having accurate V(s) in the actor-critic method.

5.1.3.3 Batch size - [5 points]

Q5.1.3.3

I would say that batch size marginally helps to improve the policy faster, and I think the improvement is non-linear, which is why we don't see the time-to-plateau gets $\frac{1}{5}$ ed.

But more data does help the experiment without reward-to-go to converge faster, since it typically needs more rollouts, i.e., more state/action/reward tuples, because it typically has higher variance.

5.2 Experiment 2 (InvertedPendulum) – [15 points total]
